

## 1. Overview

The Builder Pattern is a creational design pattern used to construct complex objects with many optional and required fields. It helps to create objects step-by-step and provides better readability, maintainability, and flexibility.

## 2. Structure

### Target Class:

```
```java
```

```
public class User {  
  
    private final String firstName;  
  
    private final String lastName;  
  
    private final int age;  
  
    private final String phone;  
  
    private final String address;  
  
  
    private User(UserBuilder builder) {  
  
        this.firstName = builder.firstName;  
  
        this.lastName = builder.lastName;  
  
        this.age = builder.age;  
  
        this.phone = builder.phone;  
  
        this.address = builder.address;  
  
    }  
}
```

```
public static class UserBuilder {  
  
    private final String firstName;  
  
    private final String lastName;  
  
    private int age;  
  
    private String phone;  
  
    private String address;  
  
  
    public UserBuilder(String firstName, String lastName) {  
  
        this.firstName = firstName;  
  
        this.lastName = lastName;  
  
    }  
  
  
    public UserBuilder age(int age) {  
  
        this.age = age;  
  
        return this;  
  
    }  
  
  
    public UserBuilder phone(String phone) {  
  
        this.phone = phone;  
  
        return this;  
  
    }  
  
  
    public UserBuilder address(String address) {  
  
        this.address = address;  
  
        return this;  
  
    }  
}
```

```
public User build() {  
  
    return new User(this);  
  
}  
  
}
```

@Override

```
public String toString() {  
  
    return "User: " + this.firstName + " " + this.lastName +  
  
    ", Age: " + this.age +  
  
    ", Phone: " + this.phone +  
  
    ", Address: " + this.address;  
  
}  
  
}  
  
...
```

### Usage Example:

```
```java  
  
public class BuilderDemo {  
  
    public static void main(String[] args) {  
  
        User user = new User.UserBuilder("John", "Doe")  
  
        .age(30)  
  
        .phone("1234567890")  
  
        .address("New York")  
  
        .build();  
  
  
        System.out.println(user);  
  
    }  
  
}
```

```
}  
  
}  
  
...
```

### 3. Boundaries and Best Practices

- Immutability: Keep the target class immutable.
- Validation: Perform field validation inside the build() method.
- Fluent Interface: Ensure each builder method returns this.
- Avoid Overuse: Use when object construction is complex.

### 4. Common Interview Questions (with Answers)

#### **Q1: What is the Builder Pattern and why is it used?**

A1: It's used to construct complex objects step-by-step. It helps in avoiding large constructors with many parameters and improves code readability.

#### **Q2: Difference between Builder and Factory Patterns?**

A2: Factory Pattern creates objects without specifying the exact class. Builder Pattern is used to build a complex object step-by-step.

#### **Q3: Advantages of the Builder Pattern?**

A3: Immutability, better readability, easier to maintain, no telescoping constructors, and object creation with optional parameters.

#### **Q4: Why not use telescoping constructors?**

A4: They become hard to read, maintain, and error-prone when many parameters are involved.

**Q5: Can the builder class be non-static?**

A5: Technically yes, but it defeats the purpose as it would require an instance of the enclosing class.

**Q6: Is Builder Pattern only for immutability?**

A6: No, it's mainly for object construction. Immutability is a commonly associated benefit.

**Q7: Builder vs Prototype Pattern?**

A7: Builder builds a fresh object step-by-step. Prototype clones an existing object.

**5. Summary**

The Builder Pattern is a powerful solution for managing complex object creation. It makes the code more readable and maintainable by separating the construction logic from the object representation.
